

S4 File. Experiment 1, preliminary analyses

We investigated whether children consistently copied the same model for both test trials or whether children switched strategies to match the method of a different model between the first and second trial. We used nonparametric tests and found that there were no order effects in the instrumental condition, $p = .62$, and in the normative condition, $p = .89$. There were also no differences in performance for choosing the competent model by gender in the instrumental, $\chi^2 (1, N= 22) = .94, p = .64$, or normative condition, $\chi^2 (1, N= 22) = .375, p = .66$. Finally, there were no differences in responses across both test boxes across conditions, $\chi^2 (1, N= 44) = .16, p = .22$.
